"Method of Producing Water-Soluble Glass Fibres"

The present invention relates to a method for the production of water soluble glass fibres and glass wool.

It is known that certain glasses, in which the usual glass former, silicon dioxide, is replaced with phosphorous pentoxide, are soluble in water and body fluids. The rate of dissolution is controlled largely by the addition of glass modifiers such as calcium oxide. In simple terms, the greater the concentration of the modifier the slower the rate of dissolution. The rate of dissolution may range from minutes through to several years.

Soluble phosphate based glasses which have demonstrated good biocompatability can incorporate inorganic metals such that a sustained release of the metals can be provided at the wound site. Such materials can also find use in mechanical applications where, for example, slow release of an anti-corrosion agent may be beneficial.

Certain applications require that the glass is in the

applications.

1 form of wool or fibres for mechanical applications such 2 as insulation wool and packaging. Thus, for example, 3 Mohr et al in "Fibre Glass" (Van Norstrand, Reinhold 4 Company, New York 1978) and Jaray in "A New Method of 5 Spinning Glass Fibres" (28th Annual SPI RP/C Institute 6 proceedings 1973, Section 3-A) describe the production 7 of wool and fibres, respectively, from molten glass. 8 The glass fibres can be used for insulation, 9 construction or even communication purposes. 10 wool also finds uses in packaging and insulation

11 12 13

14

15

16

Normally, glass fibres are produced from molten glass using traditional fibre pulling techniques; whereby filaments of high temperature molten glass (850°-1300°C) are formed into strands and stretched over pull rolls before being collected onto a reel.

17 18 19

20

21

22

23

24

25

26

27

28

29

30

31

32

Glass wool formation is similar in that the glass is initially melted in a crucible. The crucible has suitable apertures to allow filaments of glass to flow downwards, which are then "blown" into wool using jets of either steam or compressed air. Alternatively, glass wool can be formed using a flame attenuation process, developed by Owens-Corning Fibreglass Corporation circa 1940. In this process molten glass passes through a bushing stage where primary filaments approximately 1 mm wide are formed. The fibres are then aligned into an exact uniformly juxtaposed array, using a fibre guide, into a jet flame issuing from an internal combustion burner. The jet flame causes thinning and lengthening of the fibres before they are collected on a steel mesh belt.

3334

In both cases, the glass is either supplied in molten form direct from a crucible or from a temperaturegradient furnace.

Generally, water soluble glasses do not lend themselves to these traditional fibre and wool forming techniques. As an example, US Patent 4,604,097 of Graves et al

6 discloses a water soluble drawn fibre, composed

7 primarily of calcium oxide and phosphorous pentoxide.

8 The fibre produced has a very low tensile strength,

9 compared to fibres spun from non-soluble glass

10 compositions.

Further, water soluble glasses can also be chemically aggressive when molten, unlike traditional glasses where silicon dioxide is used as the glass former.

Additionally, the fibres produced are prone to thermal shock and can suffer from devitrification or crystallisation.

 To combat problems of devitrification and crystallisation, water soluble glass fibres have been previously produced in exacting conditions. Thus, for example, Zimmer et al in W092/07801 discloses drawing fibres from a water soluble glass composed primarily of phosphorus pentoxide, calcium oxide and iron oxide. In order to keep the viscosity of the glass suitable for drawing, the fibres were drawn at 1200°C. Also as a result of the chemically aggressive nature of the glass at that temperature the glass was pulled in an oxygen rich atmosphere (as high as 80% oxygen by volume). Obviously the commercial production of glass fibres under these high temperature controlled atmospheric conditions is expensive.

The problems of working with water soluble glass are compounded by the very nature of the glass. Metal oxides of elements such as lead and tellurium have

36

1 previously been used in glass as additives to affect 2 qualities of the glass; crystallisation temperature, 3 viscosity and density, for example. As a result of 4 environmental concerns and particularly when the 5 glasses are to be used in a biological application 6 these additives must be avoided and replaced by more 7 acceptable alternatives. 8 9 Therefore, it is an object of the present invention to 10 provide environmentally acceptable water soluble glass fibres with suitable mechanical properties, and to 11 12 produce said fibres under less forcing conditions. 13 14 The present invention provides a method for forming a 15 water-soluble glass fibre and/or glass wool, the method 16 comprising producing a water-soluble glass and heating 17 said glass above its melting point to form molten 18 glass, cooling at least a portion of said molten glass 19 to a pre-selected working temperature and then 20 processing said molten glass having said working 21 temperature into fibres and/or wool. 22 23 Generally, the glass is initially heated to a melting 24 temperature of 500°-1200°C, preferably 750°-1050°C. 25 The temperature is then slowly lowered to the working 26 temperature at which fibre formation occurs. 27 28 Generally, the working temperature of the glass will be 29 at least 200°C lower than the temperature at which the 30 glass is initially heated. Suitable working 31 temperatures may fall within the following ranges 400°-32 500°C, 500°-900°C (preferably 550°-700°C, more preferably 550°-650°C, especially 600°-650°C) and 800-33 34 The working temperature selected will depend upon the glass composition, but an approximate 35

indication of a suitable working temperature can be

established as hereinafter described. Depending upon the glass composition used, the working temperature may be a range of suitable temperatures. The range of working temperatures may be narrow, for example of only 10°C, so that fibre formation may occur only between the temperature of N°C to (N+10)°C. Other glass compositions may have a wider temperature range for the working temperature in which glass formation is possible.

Alternatively, the working temperature of the glass may be defined as 50-300°C above the Tg of the glass.

In order to obtain an approximate indication of the working temperature for any particular glass composition, the glass composition should be slowly heated to its melting point. As soon as the glass is molten, frequent attempts to pull the composition upwardly to form a fibre should be made, with the temperature of the composition being very gradually increased between attempts. The temperature range of the composition during which fibre formation is possible should be noted and used as a preliminary working temperature in the process of the invention.

It will be clear to those skilled in the art that the pulling speed at which the fibre is drawn off can affect the choice of working temperature and the diameter of the fibre required. Where a fibre of relatively large diameter is required, the fibre tends to be pulled more slowly and the working temperature may need to be decreased slightly. Where a fibre of relatively small diameter is required (eg a glass wool), the fibres may be drawn at the much higher pulling speed and the working temperature may need to be increased (thus lowering the viscosity of the

composition to accommodate the increased pulling
speed). Selection of the exact working temperature in
respect of any particular fibre size and composition
will be a simple matter of routine evaluation of
optimal process conditions.

6 7

8

9

10

11

12

13

14

15

16

17

18

19

20

21

22

23

With reference to the "working temperature" of the glass, the skilled person will appreciate that the furnace temperature may differ considerably from the temperature of the glass itself and indeed there may be a significant temperature gradient in the glass. Ideally the "working temperature" will be the temperature of the glass as fibre formation (ie. pulling) takes place. In many compositions however, it may not be practical to measure the temperature at the surface of the glass where pulling occurs by insertion of a temperature probe as the introduction of the probe may precipitate crystallisation of the glass. alternative is to place a temperature probe into the bushing and to monitor the bushing temperature which will be a good indicator of the glass temperature at the moment of fibre formation. Alternatively an Infra Red pyrometer may be focused onto the appropriate area of the glass and used to monitor the temperature.

24 25

26

27

28

29

30

31

32

33

34

35

36

The glass to be formed into fibres will generally be heated until molten, optionally clarified, and then cooled slowly and controllably until the appropriate working temperature is reached and fibre formation can commence. The initial heating of the glass above its melting point and the subsequent fibre formation may be carried out in a single vessel or, alternatively, the molten glass may be transferred to a vessel designed specifically for fibre formation. One way of holding the molten glass in a vessel having a bushing within its lower surface until the temperature drops to the

required working temperature is to coat or fill the 1 holes of the bushing with a material that gradually 2 melts over the period of time taken for the glass to 3 reach the temperature required. 4 5 The most important aspect of the present invention is 6 the manner in which the working temperature is reached. 7 We have found that the molten glass, which may 8 preferably be heated significantly above its melting 9 point, should be allowed to cool in a highly controlled 10 manner, the temperature being only gradually reduced 11 until the working temperature is reached. A stirrer 12 may be present to ensure that the temperature of the 13 14 whole of the molten glass is kept as uniform as 15 possible. 16 The glass is cooled to a temperature at which the glass 17 18 will not crystallise for at least the period of time 19 needed to convert the melt to fibre. This temperature is termed a "holding temperature". The rate of cooling 20 from this holding temperature is determined by the rate 21 at which the melt is consumed at the bushing and the 22 difference in temperature between the bushing 23 temperature (the working temperature) and the melt 24 25 holding temperature. 26 27 Due to low viscosity and narrow temperature band for 28 many of these compositions, control of the balance 29 between melt temperature, bushing temperature and glass 30 throughput rate is critical. 31 32 33

According to a further aspect of the present invention there is provided a composition suitable for processing into glass fibres and/or wool.

35 36

34

Phosphorous pentoxide (P_2O_5) is preferably used as the

WO 98/54104 PCT/GB98/01597

8

glass former.

1 2

Generally the mole percentage of phosphorous pentoxide in the glass composition is less than 85%, preferably less than 60% and especially between 30-60%.

6

7 Alkali metals, alkaline earth metals and lanthanoid 8 oxides or carbonates are preferably used as glass 9 modifiers.

10

11 Generally, the mole percentage of alkali metals, 12 alkaline earth metals and lanthanoid oxides or 13 carbonates is less than 60%, preferably between 40-60%.

14

Boron containing compounds (eg B_2O_3) are preferably used as glass additives.

17 18

19

Generally, the mole percentage of boron containing compounds is less than 15% or less, preferably less than 5%.

202122

23

24

Other compounds may also be added to the glass to modify its properties, for example SiO_2 , Al_2O_3 , SO_3 , sulphate ions (SO_4^{2-}) or transition metal compounds (eg. first row transition metal compounds).

30

31

32

33

34

35

36

Typically the soluble glasses used in this invention comprise phosphorus pentoxide (P_2O_5) as the principal glass-former, together with any one or more glass-modifying non-toxic materials such as sodium oxide (Na_2O) , potassium oxide (K_2O) , magnesium oxide (MgO), zinc oxide (ZnO) and calcium oxide (CaO). The rate at which the glass dissolves in fluids is determined by the glass composition, generally by the ratio of glass-modifier to glass-former and by the relative proportions of the glass-modifiers in the

glass. By suitable adjustment of the glass
composition, the dissolution rates in water at 38°C
ranging from substantially zero to 25mg/cm²/hour or more
can be designed. However, the most desirable

dissolution rate R of the glass is between 0.01 and

6 $2.0 \text{mg/cm}^2/\text{hour}$.

The water-soluble glass is preferably a phosphate glass, and preferably comprises a source of silver ions which may advantageously be introduced during manufacture as silver orthophosphate (Ag₃PO₄). glass preferably enables controlled release of silver and other constituents in the glass and the content of these additives can vary in accordance with conditions of use and desired rates of release, the content of silver generally being up to 5 mole %. While we are following convention in describing the composition of the glass in terms of the mole % of oxides, of halides and of sulphate ions, this is not intended to imply that such chemical species are present in the glass nor that they are used for the batch for the preparation of the glass.

34

35

36

The optimum rate of release of silver ions into an aqueous environment may be selected by circumstances and particularly by the specific function of the released silver. The invention provides a means of delivering silver ions to an aqueous medium at a rate which will maintain a concentration of silver ions in said aqueous medium of not less than 0.01 parts per million and not greater than 10 parts per million. In some cases, the required rate of release may be such that all of the silver added to the system is released in a short period of hours or days and in other applications it may be that the total silver be released slowly at a substantially uniform rate over a

period extending to months or even years. particular cases there may be additional requirements, for example it may be desirable that no residue remains after the source of the silver ions is exhausted or, in other cases, where the silver is made available it will be desirable that any materials, other than the silver itself, which are simultaneously released should be physiologically harmless. In yet other cases, it may be necessary to ensure that the pH of the resulting solution does not fall outside defined limits.

Generally, the mole percentage of these additives in the glass is less than 25%, preferably less than 10%.

Embodiments of the invention will be described with reference to the following non-limiting examples.

Example 1

19		Component	Mole %
20	Glass Composition		
21		Na ₂ O	31.05
22		CaO	16.00
23		= Ag₂O	3.88
24		P_2O_5	46.08
25		Na_2PO_3F	0.97
26		2A1 ₂ O ₃ .B ₂ O ₃	2.00

100 grams of the sample was heated to 900°C before being cooled and pulled at 650°C, at 25 km/hr. Overall the fibre was good; one sample was 10 km in length and 11 grams in weight, although there was some crystallisation at the pulling temperature.

1	Example 2		
2		Component	Mole %
3	Glass Composition		
4		Na ₂ O	29.51
5		CaO	15.21
6		Ag_2O	3.68
7		P_2O_5	43.80
8		$2Al_2O_3.B_2O_3$	1.90
9		Na_2PO_3F	1.90
10		$Na_2B_4O_7.10H_2O$	1.00
11		Na ₂ PO ₄	3.00

74 grams of the sample was heated to 1000°C before being cooled and pulled at 635°C at 25 km/hr. The fibre produced was ultrafine; one sample was 18 km in length and 59 grams in weight. The sample was sprayed with WD40 to prevent water absorption and to aid lubricity. There was some debris at the bottom of the crucible, but this was found to be just iron deposits from the brushing rod.

Example 3

24		Component	Mole %
25	Glass Composition		
26		Na ₂ O	34.20
27		CaO	16.15
28		P_2O_5	44.65
29		Na ₂ SO ₄	5.00

200 grams of the sample was heated to 1050°C before being cooled and pulled at 635°C at 25 km/hr. The fibre was good although there was some crystallisation at the pulling temperature.

Claims

1 2

3 1. A method for forming water-soluble glass fibres, 4 the method comprising providing a composition 5 suitable for producing a water-soluble glass and 6 heating said composition above the melting point 7 of said glass to form a molten glass, cooling at 8 least a portion of said molten glass to a pre-9 selected working temperature and then processing 10 said molten glass having said working temperature 11 into fibres.

12

A method as claimed in Claim 1 wherein said
 portion of said molten glass is cooled slowly to
 said working temperature.

16

A method as claimed in either one of Claims 1 and
 wherein said working temperature is 50-300°C
 above the Tg of the glass.

20

21 4. A method as claimed in either one of Claims 1 and 22 2 wherein said working temperature is at least 23 200°C below the temperature to which the glass is 24 initially heated.

25

26A method as claimed in any one of Claims 1 to 4wherein glass wool is formed.

28

29 6. A method as claimed in any one of Claims 1 to 5
30 wherein phosphorous pentoxide is used as the glass
31 former.

32

A method as claimed in any one of Claim 6 wherein
 boron containing compounds are used as glass
 modifiers.

36

37 8. A method as claimed in Claim 7 wherein $B_2 0_3$ is used as a glass modifier at a mole percentage of 15% or

less.

Namethod as claimed in any one of Claims 1 to 8
wherein said glass is a silver-ion releasing
glass.

10. A method as claimed in Claim 9 wherein silver orthophosphate is added during manufacture of the glass as a source of silver ions.

United States Patent Application

COMBINED DECLARATION AND POWER OF ATTORNEY

Attorney's	Docket	Number	1066-99	
------------	--------	--------	---------	--

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name.

I believe I am an original, first and joint inventor of the subject matter which is claimed and for which a patent is sought on the invention entitled:

"Method of Producing Water-Soluble Glass Fibres"

the specification of which:

[c] was filed as a PCT international application Number PCT/GB98/01597 on 1 June 1998.

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, Section 1.56(a).

I hereby claim foreign priority benefits under Title 35, United States Code, Section 119 of any foreign application(s) for patent or inventor's certificate or of any PCT international application(s) designating at least one country other than the United States of America listed below, and have also identified below any foreign application(s) for patent or inventor's certificate or any PCT international application(s) designating at least one country other than the United States of America filed by me on the same subject matter and having a filing date before that of the application(s) of which priority is claimed:

COUNTRY	APPLICATION NUMBER	DATE OF FILING	PRIORITY CLAIMED
		(day, month, year)	Yes/No
Vnited Kingdom	9711178.5	31 May 1997	Yes

POWER OF ATTORNEY: As a named inventor, I hereby appoint the following attorney(s) and/or agent(s) to prosecute this application and transact all business in the patent and Trademark Office connected therewith:

Charles N. Quinn (Registration No 27,223).

SEND CORRESPONDENCE TO:

CHARLES N. QUINN, ESQ.

1601 Market Street, Suite 720

Philadelphia, PA 19103-2307

E-mail: cquinn@ddhs.com

Voice: 215-563-4100 x223

Fax: 215-563-4044
